

Description

The F1451 is a High Gain / High Linearity 450MHz to 1100MHz TX Digital Variable Gain Amplifier used in transmitter applications.

The F1451 TX DVGA provides 32dB maximum gain with +41.5dBm OIP3 and 3.6dB noise figure. Up to 29.5dB gain control is achieved using the combination of a digital step attenuator (DSA) and a K_{LIN}^{TM} RF Digital Gain Amplifier. This device uses a single 5V supply and 185mA of I_{CC} .

This device is packaged in a 6 × 6 mm, 28-pin VFQFPN with 50Ω single-ended RF input and RF output impedances for ease of integration into the signal-path.

Competitive Advantage

In typical Base Stations, RF VGAs are used in the TX traffic paths to drive the transmit power amplifier. The F1451 TX DVGA offers very high reliability due to its construction from a monolithic silicon die in a QFN package. The F1451 is configured to provide an optimum balance of noise and linearity performance consisting of a K_{LIN}^{TM} RF amplifier, digital step attenuator (DSA) and a PA driver amplifier. The K_{LIN}^{TM} amplifier maintains the OIP3 and output P1dB performance over an extended attenuation range when compared to competitive devices.

Typical Applications

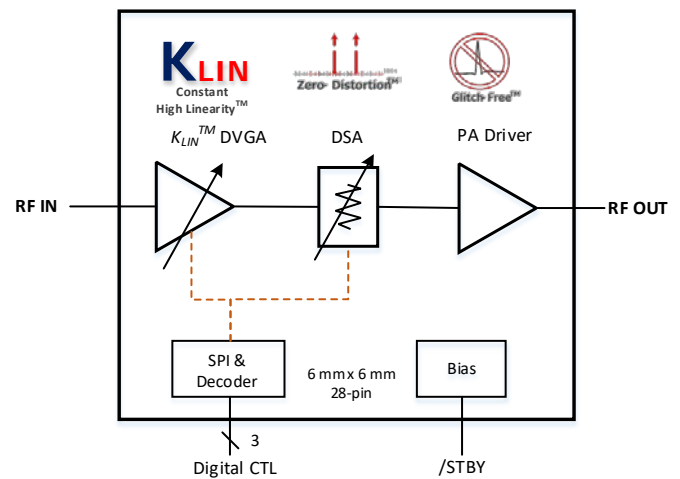

- Multi-mode, Multi-carrier Transmitters
- WiMAX and LTE Base Stations
- UMTS/WCDMA 3G Base Stations
- PHS/PAS Base Stations
- Public Safety Infrastructure

Features

- Broadband 450MHz to 1100MHz
- 32dB maximum gain
- 3.6dB NF at maximum gain (900MHz)
- 29.5dB total gain control range, 0.5dB step
- < 2dB overshoot between gain transitions
- Maintains flat +23dBm OP1dB for more than 13dB gain adjustment range
- Maintains flat +41dBm OIP3 for more than 15dB gain adjustment range
- SPI interface for DSA control
- Single 5V supply voltage
- $I_{CC} = 185\text{mA}$
- Up to +105°C T_{CASE} operating temperature
- 50Ω input and output impedance
- Standby mode for power savings
- Pin compatible 2100MHz and 2700MHz versions
- 6 × 6 mm, 28-VFQFPN package

Pin Descriptions

Table 1. Pin Descriptions

Number	Name	Description
1	CSb	Chip select input: 1.8V or 3.3V logic compatible.
2	DATA	Data input: 1.8V or 3.3V logic compatible.
3	CLK	Clock input: 1.8V or 3.3V logic compatible.
4 ^a	RSET	Connect 2.0kΩ external resistor to GND to set amplifier bias.
5, 7, 15, 17, 21, 23, 27	GND	Pins internally tied to exposed paddle. Connect to ground on PCB.
6	RFIN	RF input internally matched to 50Ω. Must use external DC block.
8, 9, 10, 11, 12, 13, 18, 19, 20, 22, 24, 25, 26	NC	No internal connection. These pins can be left unconnected, voltage applied, or connected to ground (recommended).
14	/STBY	Standby pin. Device will be placed in standby mode when pin 14 is set to a logic low or when pin 14 is left floating (pulled low via internal high impedance to GND). In standby mode, SPI circuitry is still active. With a logic high applied to pin 14 the part is set to full operation mode.
16	RFOUT	RF output internally matched to 50Ω. Must use external DC block.
28	VCC	5V Power Supply. Connect to V _{CC} and use bypass capacitors as close to the pin as possible.
	EP	Exposed Pad. Internally connected to GND. Solder this exposed pad to a PCB pad that uses multiple ground vias to provide heat transfer out of the device into the PCB ground planes. These multiple vias are also required to achieve the noted RF performance.

- a. External resistor on pin 4 used to optimize the overall device for DC current and linearity performance across the entire frequency band.

Absolute Maximum Ratings

Stresses above those listed below may cause permanent damage to the device. Functional operation of the device at these or any other conditions above those indicated in the operational section of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

Table 2. Absolute Maximum Ratings

Application Information

The F1451 has been optimized for use in high performance RF applications from 450MHz to 1100MHz but in general has a much wider band which is shown in the Typical Performance Characteristics.

Power Up Attenuation Setting

When the part is initially powered up, the default VGA setting is the 29.5dB [000000] attenuation state.

Chip Select (CSb)

When CSb is set to logic high, the CLK input is disabled. When CSb is set to logic low, the CLK input is enabled and the DATA word can be programmed into the shift registers. The programmed word is then latched into the F1451 on the CSb rising edge (refer to Figure 53). The operation of the SPI bus is independent of the /STBY pin setting (see Standby Mode section below).

Standby Mode (/STBY)

The F1451 has a power down feature for power savings which is on Pin 14. For normal operation pin 14 must be set to a logic high. When a logic low is applied to pin 14 the amplifier is placed in standby mode. The Standby mode is a high isolation state. The level of this isolation is not specified and is dependent on the device and attenuation state. In Standby mode the SPI bus is operational and the device attenuation setting can be programmed. Therefore, the device will present the desired attenuation when it is enabled.

Power Supplies

A common V_{CC} power supply should be used for all power supply pins. To minimize noise and fast transients de-coupling capacitors to all supply pins. Supply noise can degrade noise figure and fast transients can trigger ESD clamps causing them to fail. Supply voltage change or transients should have a slew rate smaller than $1V / 20\mu s$. In addition, all control pins should remain at 0V ($\pm 0.3V$) while the supply voltage ramps or while it returns to zero.

Control Pin Interface

If control signal integrity is a concern and clean signals cannot be guaranteed due to overshoot, undershoot, ringing, etc., the following circuit at the input of each control pin is recommended. This applies to SPI and control pins 1, 2, 3 and 14 as shown below. Note the recommended resistor and capacitor values do not necessarily match the EV kit BOM for the case of poor control signal integrity. For multiple devices driven by a single control line, the component values will need to be adjusted accordingly so as not to load down the control line.

Evaluation Kit Operation

Standby

Connector J6 allows the F1451 to be put into the standby mode. Connecting J6 pin 2 (the center pin) to V_{CC} the amplifier will be placed in normal operating mode. To put the F1451 into standby mode for very low power consumption ground J6 pin 2 (the center pin). If J6 pin 2 (the center pin) is left open, then the F1451 will default to the standby mode.

Serial Programming Pins

Connector J7 pins 1, 2, 4, 6, and 8 are ground. Pin 3 is DATA, pin 5 is Clock (CLK), pin 7 is Chip Select (CSB).
