## Hysteretic Buck High Brightness LED Driver with Internal Switch UM1360Y SOT89-5

## General Description

The UM1360 is a PWM step-down converter with internal power switch, designed for driving single or multiple series connected LEDs efficiently from a voltage source higher than the LED voltage. The UM1360 can drive up to 10 series connected LEDs. The device operates from an input supply between 6 V and 40 V and employs hysteretic control with a high side current sense resistor to set the constant output current up to 1A. The device is well suited for applications requiring a wide input range. The high side current sensing and an integrated current sensing circuitry minimize the number of external components while delivering an accurate average output current. Depending upon supply voltage and external components, this device can provide up to 30 watts of output power.
Output current can be adjusted below the set value, by applying an external control signal to the VSET pin. The VSET pin will accept either a DC voltage or a PWM waveform. Dedicated pulse width modulation (PWM) input enables pulsed LED dimming over a wide range of brightness levels. A hysteretic control method ensures excellent input supply rejection and fast response during load transients and PWM dimming.
Applying a voltage of 0.2 V or lower to the VSET pin turns the output off and switches the device into a low current standby state. The UM1360 employs spread spectrum technique to greatly reduce its interference to other part of the system.
The UM1360 comes in small SOT89-5 package. It is ideal for industrial and general lighting applications.

## Applications

- Low Voltage Halogen Replacement LEDs
- Low Voltage Industrial Lighting
- LED Back-Side Lighting
- Illuminated Signs
- DC/DC or AC/DC LED Driver Application
- General Purpose, Constant Current Source

## Features

- Hysteretic Control with High Side Current Sensing
- Integrated $40 \mathrm{~V} 0.5 \Omega$ NDMOS
- Up to $98 \%$ Efficiency
- Wide Input Voltage Range: 6 V to 40 V
- 50V Transient Capability
- $\pm 5 \%$ LED Current Accuracy
- Adjustable Constant LED Current
- Single Pin On/Off and Brightness Control Using DC Voltage or PWM
- Spread Spectrum Driver
- Over Temperature, Open Circuit LED Protection
- Up to 1 MHz Switching Frequency
- Pb-Free SOT89-5 Package

Output Current Change vs. Temperature (L1=47 $\mu \mathrm{H}$, Rs=0.33 )

## Applications Information

## Setting Nominal Average Output Current with External Resistor $\mathbf{R}_{\mathbf{S}}$

The nominal average output current in the $\mathrm{LED}(\mathrm{s})$ is determined by the value of the external current sense resistor $\left(\mathrm{R}_{\mathrm{S}}\right)$ connected between VIN and ISENSE and is given by:
$\mathrm{I}_{\text {OUTnom }}=0.1 / \mathrm{R}_{\mathrm{S}}$ [for $\mathrm{R}_{\mathrm{S}} \geq 0.1 \Omega$ ]
The table below gives values of nominal average output current for several preferred values of current setting resistor (Rs) in the typical application circuit as shown on page 5.

| Rs ( $\mathbf{\Omega})$ | Nominal Average Output Current (mA) |
| :---: | :---: |
| 0.1 | 1000 |
| 0.13 | 760 |
| 0.15 | 667 |
| 0.3 | 333 |

The above values assume that the VSET pin is floating or applied with a voltage higher than 2.5 V (must be less than 5 V ). Note that $\mathrm{Rs}=0.1 \Omega$ is the minimum allowed value of sense resistor under these conditions to maintain switch current below the specified maximum value. It is possible to use different values of Rs if the VSET pin is driven from an external voltage. (See next section).

## Output Current Adjustment by External DC Control Voltage

The VSET pin can be driven by an external DC voltage ( $\mathrm{V}_{\mathrm{EN}}$ ), as shown, to adjust the output current to a value below the nominal average value defined by Rs.

The average output current is given by:
$\mathrm{I}_{\text {OUT }}=\left(0.1 * \mathrm{~V}_{\mathrm{EN}}\right) /(2.5 * \mathrm{Rs})$ [for $0.3 \mathrm{~V}<\mathrm{V}_{\mathrm{EN}}<2.5 \mathrm{~V}$ ]
Note that $100 \%$ brightness setting corresponds to:
$\left(2.5 \mathrm{~V} \leq \mathrm{V}_{\mathrm{EN}} \leq 5 \mathrm{~V}\right)$

## Output Current Adjustment by PWM Control

A Pulse Width Modulated (PWM) signal with duty cycle PWM can be applied to the VSET pin, as shown below, to adjust the output current to a value below the nominal average value set by resistor Rs:
$\mathrm{I}_{\text {OUT }}=(0.1 * \mathrm{D}) / \mathrm{R}_{\mathrm{S}} \quad\left(0 \leq \mathrm{D} \leq 100 \%, 2.5 \mathrm{~V}<\mathrm{V}_{\text {pulse }}<5 \mathrm{~V}\right)$
$\mathrm{I}_{\text {OUT }}=\left(\mathrm{V}_{\text {pulse }} * 0.1 * \mathrm{D}\right) /\left(2.5 * \mathrm{R}_{\mathrm{S}}\right) \quad\left(0 \leq \mathrm{D} \leq 100 \%, 0.5 \mathrm{~V}<\mathrm{V}_{\text {pulse }}<2.5 \mathrm{~V}\right)$

PWM dimming provides reduced brightness by modulating the LED's forward current between $0 \%$ and $100 \%$. The LED brightness is controlled by adjusting the relative ratios of the on time to the off time. A $25 \%$ brightness level is achieved by turning the LED on at full current for $25 \%$ of one cycle. To ensure this switching process between on and off state is invisible by human eyes, the switching frequency must be greater than 100 Hz . When above 100 Hz , the human eyes average the on and off times, seeing only an effective brightness that is proportional to the LED's on-time duty cycle. The advantage of PWM dimming is that the forward current is always constant, therefore the LED color does not vary with brightness as it does with analog dimming. Pulsing the current provides precise brightness control while preserving the color purity.

## Capacitor Selection

A low ESR capacitor should be used for input decoupling, as the ESR of this capacitor appears in series with the supply source impedance and lowers overall efficiency. This capacitor has to supply the relatively high peak current to the coil and smooth the current ripple on the input supply. A minimum value of $4.7 \mu \mathrm{~F}$ is acceptable if the input source is close to the device, but higher values will improve performance at lower input voltages, especially when the source impedance is high. The input capacitor should be placed as close as possible to the IC.
For maximum stability over temperature and voltage, capacitors with X7R, X5R, or better dielectric are recommended. Capacitors with Y5V dielectric are not suitable for decoupling in this application and should NOT be used.

## Inductor Selection

Recommended inductor values for the UM1360 are in the range $27 \mu \mathrm{H}$ to $220 \mu \mathrm{H}$. Higher values of inductance are recommended at higher supply voltages in order to minimize errors due to switching delays, which result in increased ripple and lower efficiency. Higher values of inductance also result in a smaller change in output current over the supply voltage range. The inductor should be mounted as close to the device as possible with low resistance connections to the LX and VIN pins. The chosen coil should have a saturation current higher than the peak output current and a continuous current rating above the required mean output current. Suitable coils for the UM1360 are listed in the table below:

| Load Current | Inductor | Saturation Current |
| :---: | :---: | :---: |
| $\mathrm{I}_{\mathrm{OUT}}>1 \mathrm{~A}$ | $27-47 \mu \mathrm{H}$ | 1.3-1.5 Times of Load Current |
| $0.8 \mathrm{~A}<\mathrm{I}_{\mathrm{OUT}} \leq 1 \mathrm{~A}$ | $33-82 \mu \mathrm{H}$ |  |
| $0.4 \mathrm{~A}<\mathrm{I}_{\mathrm{OUT}} \leq 0.8 \mathrm{~A}$ | $47-100 \mu \mathrm{H}$ |  |
| $\mathrm{I}_{\mathrm{OUT}} \leq 0.4 \mathrm{~A}$ | $68-220 \mu \mathrm{H}$ |  |

| Order <br> Code | $\mathbf{L}(\boldsymbol{\mu H})$ | Size | DCR <br> $(\mathbf{m} \boldsymbol{\Omega})$ | Saturation <br> Current $(\mathbf{m A )}$ | Manufacturer |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 744066330 | 33 | 1038 | 92 | 1800 |  |
| 7447714470 | 47 | 1050 | 82.5 | 2.5 | www.we-online.com |
| 7447714680 | 68 | 1050 | 110 | 2200 |  |
| 7447714101 | 100 | 1050 | 165 | 1800 |  |

The inductor value should be chosen to maintain operating duty cycle and switch 'on'/'off' times within the specified limits over the supply voltage and load current range. The following equations can be used as a guide.
LX Switch 'On' time
$\mathrm{T}_{\mathrm{ON}}=(\mathrm{L} 1 * \Delta \mathrm{I}) /\left(\mathrm{V}_{\mathrm{IN}}-\mathrm{V}_{\mathrm{LED}}-\mathrm{I}_{\mathrm{LED}} *\left(\mathrm{R}_{\mathrm{S}}+\mathrm{R}_{\mathrm{L}}+\mathrm{R}_{\mathrm{LX}}\right)\right)$
LX Switch 'Off' time
$\mathrm{T}_{\mathrm{OFF}}=(\mathrm{L} 1 * \Delta \mathrm{I}) /\left(\mathrm{V}_{\mathrm{LED}}+\mathrm{V}_{\mathrm{D}}+\mathrm{I}_{\mathrm{LED}} *\left(\mathrm{R}_{\mathrm{S}}+\mathrm{R}_{\mathrm{L}}\right)\right)$
Where:
L 1 is the coil inductance $(\mathrm{H})$.
$\mathrm{R}_{\mathrm{L}}$ is the coil resistance ( $\Omega$ ).
$\mathrm{R}_{\mathrm{S}}$ is the current sense resistance ( $\Omega$ ).
$\mathrm{I}_{\text {LED }}$ is the required LED current (A).
$\Delta \mathrm{I}$ is the coil peak-peak ripple current (A) \{internally set to $\left.0.3 \times \mathrm{I}_{\text {LED }}\right\}$.
$\mathrm{V}_{\text {IN }}$ is the supply voltage ( V ).
$\mathrm{V}_{\mathrm{LED}}$ is the total LED forward voltage ( V ).
$\mathrm{R}_{\mathrm{LX}}$ is the switch resistance $(\Omega)\{=0.5 \Omega$ nominal $\}$.
$\mathrm{V}_{\mathrm{D}}$ is the diode forward voltage at the required load current $(\mathrm{V})$.

## Diode Selection

For maximum efficiency and performance, the rectifier (D1) should be a fast low capacitance Schottky diode with low reverse leakage at the maximum operating voltage and temperature.
They also provide better efficiency than silicon diodes, due to a combination of lower forward voltage and reduced recovery time.
It is important to select parts with a peak current rating above the peak coil current and a continuous current rating higher than the maximum output load current. It is very important to consider the reverse leakage of the diode when operating above $85^{\circ} \mathrm{C}$. Excess leakage will increase the power dissipation in the device and if close to the load may create a thermal runaway condition.
The higher forward voltage and overshoot due to reverse recovery time in silicon diodes will increase the peak voltage on the LX output. If a silicon diode is used, care should be taken to ensure that the total voltage appearing on the LX pin including supply ripple, does not exceed the specified maximum value.

## PCB Layout Guidelines

Careful PCB layout is critical to achieve low switching losses and stable operation. Minimize ground noise by connecting high current ground returns, the input bypass capacitor ground lead, and the output filter ground lead to a single point. Place Rs as close as possible to the ISENSE and VIN. For better noise immunity, a Kelvin connection is strongly recommended between ISENSE and Rs.
